KACH CANADA LTD.

Report Information

Prepared for review as part of a pilot emissions data readiness and reporting workflow. This draft export is not approved, verified, certified, o

Reporting Boundary

Detailed source, version, confidence level, and assumptions are provided in the Factor Details / Assumptions section below.

Calculation Quality Summary

[illegible] Review

[illegible] calculated GHG emissions total by design. Some additional records require review

[illegible] Threshold Reference

Methodology and Limitations

Calculation Traceability

This section [illegible] report methods used to create the activity records included in this pilot report. Detailed [illegible]

[illegible] categories contributing the largest share of current estimated emissions. Hotspot analysis helps identify where the organization may want to focus first for factor validation, data quality improvement, and, where estimates are confirmed, reduction planning.

Canada / federal context: 10,000 t CO2e/year per facility is shown as a general screening reference only.

Alberta only: 100,000 t CO2e/year per facility is used only when a facility row has Alberta jurisdiction.

Threshold screening only. This does not constitute regulatory compliance advice.

[illegible] CarbonLite [illegible] stage workflow: Define Reporting Boundary, Collect & Upload Source Data, Review & Resolve Data Issues, Validate Factors & Calculations, Review Results, Generate & Review Report.

Hotspot analysis only includes records that were successfully calculated. Records requiring review, tracked-only metrics, missing factors, invalid units, or missing jurisdiction are excluded from hotspot totals and listed separately.

Emissions are calculated from imported or manually entered activity data and configured emission factors. CarbonLite applies factor matching based on activity type, unit, jurisdiction, and reporting year.

Top Emissions Hotspot: Electricity

Electricity contributes 71.70% of calculated emissions. Consider this category for reduction planning because it represents a large share of calculated emissions.

Records without valid factors, units, quantities, dates, or required jurisdiction are excluded from emissions totals and listed as records requiring review. Tracked metrics are not included in calculated emissions totals.

Source documents, source references, and factor metadata should be reviewed before using report outputs for internal, consultant, or external reporting workflows.

Electricity and Natural Gas together represent 92.15% of calculated emissions.

This report was generated using CarbonLite Pilot Demo v0.1 for emissions data readiness and workflow review purposes only. It is not a certified GHG emissions report and does not constitute regulatory compliance advice, third-party verification, audit assurance, or carbon credit eligibility determination. Emission factors, assumptions, and calculations should be reviewed by qualified sustainability professionals before formal use.
